PortIQ – AI-Powered Portfolio Intelligence

AI Collaboration and Individual Contribution Statement

MBACCZG583 – Management of AI Products

Submitted by:

1. AI Collaboration

Purpose

Artificial Intelligence (AI) tools were used throughout this capstone project to accelerate ideation, documentation and software implementation. AI was used as a productivity assistant to improve efficiency, while all product management decisions, business judgement and final deliverables remained under the author's control.

The project followed a human-led approach in which AI supported execution, but all strategic, business and product decisions were defined, validated and approved by the author.

AI Tools Used

ChatGPT

ChatGPT was primarily used as a strategic product management assistant to support brainstorming, drafting and refinement activities based on detailed direction and inputs provided by the author.

Its contribution included:

- Brainstorming and refining the initial product idea.
- Preparing draft versions of the overall product strategy based on the author's direction.
- Preparing draft versions of the product vision and value proposition based on the author's inputs.
- Preparing draft versions of the business model, monetisation approach and unit economics based on the author's design decisions.
- Preparing draft versions of the Executive Summary, Final Report and Presentation based on content defined by the author.
- Reviewing written content for structure, clarity and consistency.

Claude

Claude was primarily used as a software implementation assistant.

Its contribution included:

- Developing the React-based prototype.
- Building reusable UI components.
- Implementing application routing and navigation.

- Developing the Dashboard, Portfolio, Clients, Projects and Reports modules.
- Implementing the PortIQ Copilot interface.
- Supporting UI refinements, branding updates and prototype packaging.

AI Usage Principles

AI-generated outputs were never accepted without review.

Every recommendation, design suggestion, implementation and document was critically reviewed, challenged, refined and validated before being included in the final submission.

AI was used to improve productivity and accelerate execution rather than replace independent product management judgement or decision making.

2. Individual Contribution Statement

This capstone project represents my independent work as an individual submission.

While AI tools supported documentation and software implementation, the complete product conception, product management direction and final deliverables were defined, validated and approved by me.

My individual contribution included:

- Identifying and validating the business problem.
- Selecting the product idea and defining the overall product vision.
- Identifying the target users and defining the customer value proposition.
- Defining the Jobs-to-be-Done (JTBD).
- Designing the complete end-to-end product workflow and user experience.
- Defining the MVP scope, release strategy and product roadmap.
- Preparing the PRD-lite and defining feature prioritization.
- Designing the portfolio data model, including the required business entities, relationships and data attributes.
- Defining every business KPI, financial metric, calculation formula, portfolio rule and margin strategy used throughout the prototype.

- Designing the synthetic portfolio dataset used by the MVP and ensuring that all business calculations and outputs were logically consistent.
- Identifying realistic enterprise data sources, integration points and operational assumptions for a production deployment.
- Designing the AI interaction model, orchestration layer, trust model and explainability approach.
- Defining the MVP architecture and future enterprise architecture.
- Designing the evaluation framework, business success metrics and launch criteria.
- Developing the business economics, commercial value proposition, monetization approach, unit economics and scaling strategy.
- Identifying ethical considerations, governance controls, risk mitigation measures and launch blockers.
- Continuously reviewing, validating and refining all AI-generated outputs for technical correctness, business relevance and alignment with the assignment requirements.
- Planning the product releases, validating prototype behaviour and integrating all deliverables into a complete submission package.

The React prototype was implemented with AI assistance. However, the functional scope, business logic, portfolio calculations, user experience, AI workflow, product behaviour and overall product direction were continuously directed, refined and validated by me throughout the project.

I therefore accept full responsibility for the originality, quality and academic integrity of this submission. AI tools were used responsibly as productivity assistants to accelerate execution and documentation but did not replace independent analysis, product management judgement or decision making.

Declaration

I declare that this submission represents my own work. Artificial Intelligence tools were used responsibly to support ideation, drafting and software implementation. All product decisions, business assumptions, validations, reviews and final approvals were performed by me.

I confirm that all product decisions, business analysis, architecture, feature definition and final deliverables were independently reviewed, validated and approved by me. AI tools were used solely as development and documentation assistants, while all strategic, technical and managerial decisions remained my own.
